

Section 5: Files and Lists

Index Game

As a warmup, read this code and play the game a few times. Use this mental model of the list:

Value:	'Julie'	'Mehran'	'Simba'	'Ayesha'	'Karel'
Index:	0	1	2	3	4

Heads Up

Our next goal is to learn how to read data from files. Loading data from a file can be useful for many final projects. Write a program that runs a console version of the phone game Heads Up!

How the game is played remotely:

When it is your turn, close your eyes.

A word will be displayed in the HeadsUp program.

The rest of the section will try and describe it without saying the word.

You have to guess the word as quickly as possible.

Milestones:

Milestone #1: First, load all of the words from the file `cswords.txt` into a list.

Milestone #2: Then, show a randomly chosen word from the list

Milestone #3: Repeat: wait for the user to hit enter, then show another word.

Helpful code:

This code reads a file line by line and prints each line. Modify it to construct a list:

```
with open('words.txt') as file:
    for line in file: # for-each loop gives lines one at a time
        print(line.strip()) # strip removes whitespace at the start or end
```

This code selects a random element from a list (in this case the one with name `my_list`)

```
chosen_value = random.choice(my_list) # comes with 'import random'
```

Your final project could be a game like this!

(After Section) Covid-19 Data Science

Even though the section isn't long enough for this problem, we are including it so that you can see how the file reading and lists allow for data analysis.

This course exists as a way to give us all a means to improve ourselves during the time of COVID-19. A big component of our global response are "models", often written in Python, which predict how the disease will progress. In this problem we will take small steps towards working with that data. Much of the Covid-19 data from different countries is public.

For example we provide you with a file `countries/Italy.txt` which lists the total number of confirmed cases in Italy, one value per day, starting on Jan 22nd, 2020 and going up until May 12, 2021. This is real data provided by Johns Hopkins University.

Italy.txt

```
0 # There were 0 confirmed cases up until Jan 22nd, 2020
0 # There were 0 confirmed cases up until Jan 23rd, 2020
0 # There were 0 confirmed cases up until Jan 24th, 2020
... # the file has 478 lines!
4139160 # There have been 4,139,160 cases up until May 12th, 2021
```

Challenge #1: Load all the values from the file into a list of integers.

Challenge #2: Count the number of non-zero values in the file (this is days since first case)

Challenge #3: Create a list which stores how many new cases there were each day (new cases on a given day are: total cases on that day - total cases on the previous day)

These challenges are straight forward, but are a good first step into processing data via code.

In the starter code we include similar files for all reported countries.

There are a lot of interesting questions that researchers are trying to answer. Can you tell if a country has turned the tide on the current wave of COVID-19? How can we predict the future number of cases? Can you find external data that helps explain the number of infections? These are unsolved problems, though you are welcome to explore the data using python and look for clues.

You could work on an analysis of this data for your final project.
